

ABSTRACT

In a telecommunication network, a switching system routes a call to a service platform.

The service platform transfers a prompt message over the call, collects caller-entered information from a caller over the call in response to the prompt message, and transfers

5 the caller-entered information to an SCP system. The SCP system transfers the caller-entered information to a destination processor, processes a destination routing code from the destination processor to determine a destination routing instruction, and transfers the destination routing instruction to the switching system. The switching system routes the call to a destination in response to the destination routing instruction.
